

Introduction to AJAX Final Project

There are many websites which need to provide suggestions to users typing in a text field. These websites typically do so to ensure input element quality and help generate a more friendly user-experience. One such example is Google Maps. When you begin typing an address, the address shows up in a drop down box below the input element.

Project Requirements

Use the same database that you had before but create a suggestion box like the one above for cities in the database. Make sure that the input box's text is being searched against cities, zip codes, and states. If you find it to increase usability, add other fields to the search term.

Lastly, when someone clicks on one of the entries in the suggestion box, simply fill the text box with that entire line. The format for the suggestion box should read:

City, State, Zip

Example

Waltham, MA 01604
